Name	ID3

## ECS 452: Digital Communication Systems

2017/2

HW 5 — Due: April 10, 4 PM

Lecturer: Prapun Suksompong, Ph.D.

## Instructions

(a) This assignment has 6 pages.

(b) (1 pt) Work and write your answers directly on these provided sheets (not on other blank sheet(s) of paper). Hard-copies are distributed in class.

(c) (1 pt) Write your first name and the last three digits of your student ID on the upper-right corner of this page.

(d) (8 pt) Try to solve all non-optional problems.

(e) Write down all the steps that you have done to obtain your answers. You may not get full credit even when your answer is correct without showing how you get your answer.

**Problem 1.** Consider a single-parity-check linear code. For each of the data block below, find the corresponding codeword.

<u>b</u>	<u>X</u>
010	0101
111	1111
001	0011

 We simply add one bit to the end to make even number of 1s in the codeword. Note that we use even parity because the code is assumed to be linear.

Problem 2. For each of the codes below, check whether it is a linear code.

(a)  $C = \{000, 001, 100, 101\}$ 

	⊕	د	<u>-</u>
	<u>c</u> (1)	<u>د ۲۹</u> ۶	ددی
,	دري		⊆ <sup>(2)</sup>
(b) C	$2 = \{0\}$	00, 10	0, 110, 111

Yes. The sum of any two codewords in the collection is still inside the collection.

We have shown in class that this checking can be performed in two steps:

1) check that the zero codeword is in the collection

2) check that the sum of any distict non-zero codewords in the collection is still inside the

collection

100 + 110 = 010 €C

(c)  $C = \{001, 100, 101\}$ 

000 is not a member. Any linear code must contains the zero codeword.

**Problem 3.** Consider a block code whose generator matrix is

$$\mathbf{G} = \begin{bmatrix} 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 & 1 & 0 \end{bmatrix} \} \mathbf{k} = \mathbf{3}$$

(a) Find the dimension k of this code.

k = 3 <-----

(b) Find its code rate.

$$=\frac{k}{n}=\frac{3}{6}$$

- (c) Suppose the message is  $\underline{\mathbf{b}} = [1\ 0\ 1]$ . Find the corresponding codeword  $\underline{\mathbf{x}}$ . There are several equivalent ways to approach this problem.
- 1) We can simply use  $\underline{\mathbf{z}} = \underline{\mathbf{b}} \, \mathbf{G} = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix}.$ 2) Recall that  $\underline{\mathbf{b}} \, \mathbf{G} = \begin{bmatrix} \overline{\mathbf{Z}} \, \mathbf{b}_{1} \, \mathbf{g}^{(1)} + (\mathbf{z} \, \mathbf{g}^{(2)}) + (\mathbf{z} \, \mathbf{g}^{(2)}) + (\mathbf{z} \, \mathbf{g}^{(2)}) = \underline{\mathbf{g}}^{(1)} \oplus \underline{\mathbf{g}}^{(2)} = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 & 1 \end{bmatrix}.$ The jth row of  $\underline{\mathbf{G}}$ 
  - (d) For each of the following vectors, indicate whether it is a valid codeword for this code.

If yes, find the message b that produces it. If no, state your reason.

(i) [011101]

(ii) [011101]

(iii) [110111]

(iii) [110111]

(iii) [110111]

(iii) [110111]

(iii) [110111]

(iii) [100111]

(ive how that if it is a valid codeword, the first three bits must be b.

(ive how that if it is a valid codeword in the same as the value in the given vector. Therefore no, the given vector is a valid codeword.

(ive how that if it is a valid codeword in the same as the value in the given vector. Therefore no, the given vector is not the same as the value in the given vector. Therefore no, the given vector is not a valid codeword.

(ive how that in the given vector is a valid codeword.

(ive how that in the given vector is a valid codeword.

(ive how that in the given vector is a valid codeword.

(ive how that in the given vector is a valid codeword.

(ive how that in the given vector is a valid codeword.

(ive how that in the given vector is a valid codeword.

(ive how that in the given vector is a valid codeword.

**Problem 4.** Consider a block code whose codewords are generated by  $\underline{\mathbf{x}} = \underline{\mathbf{b}}\mathbf{G}$  where  $\underline{\mathbf{b}}$  is the data block and

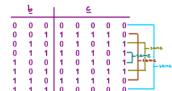

$$\mathbf{G} = \left[ \begin{array}{ccccc} 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 & 0 \end{array} \right]$$

Let the row vector  $\underline{\mathbf{g}}^{(i)}$  represents the *i*th row of  $\mathbf{G}$ . Observe that  $\underline{\mathbf{g}}^{(3)} = \underline{\mathbf{g}}^{(1)} \oplus \underline{\mathbf{g}}^{(2)}$ . Why is this bad?

The codewords for 110 and 001 are the same. So, even without bit corruption in the observed vector, the receiver can't distinguish these two cases.

Remark: There are three rows in the generator matrix; hence, k = 3 and each message block has 3 bits. For no ambiguity at the receiver, we should have 2 = 8 distinct codewords. The observation above shows that some different message blocks map to the same codeword. In fact, this code has only 4 distinct codewords.

5-2

**Problem 5.** Consider each of the block codes whose codebooks are provided below. For each code, is the code a linear code that is generated by a generator matrix? If yes, find the corresponding generator matrix. If no, provide a counter-example to support your conclusion.

(a)

رباو

We read the structure of the bits in the codewords:

$$c_1 = b_1 \oplus b_2$$
  $c_3 = b_1 \oplus b_2 \oplus b_3$   
 $c_4 = b_3$   
 $c_5 = b_1$ 

We then check the rest of each column whether all the bits satisfy the above structure or not.

Here, all the bits satisfy the above structure.

Yes, it is a linear code.

$$G = \begin{bmatrix} 9^{(1)} \\ 9^{(2)} \\ 9^{(1)} \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 \end{bmatrix}$$

(b)

We read the structure of the bits in the codewords:

$$C_1 = b_1 \bigoplus b_2 \qquad C_3 = b_1 \bigoplus b_2 \bigoplus b_3$$

$$C_4 = b_3$$

$$C_9 = b_2$$

We then check the rest of each column whether all the bits satisfy the above structure or not.

→ This bit does not satisfy こ 。 - ┗ • 🗗 🕀 Ե • • • .

The corresponding message is 101.

This part is not needed for the second conclusion below.

No the code is not linear. Furthermore, if the code is produced by a generator matrix G, then, when  $b^{(1)} = [100] \text{ and } b^{(2)} = \Gamma$ The corresponding  $b^{(1)} = [100] \text{ and } b^{(2)} = [0\ 1\ 0].$  The corresponding codeword for  $b^{(1)} + b^{(2)}$  must be  $(b^{(1)} \oplus b^{(2)}) G = b^{(1)}G \oplus b G = 11100 \oplus 00110 = 11010 \neq 11110$ code mord

for  $b^{(2)}$ for  $b^{(2)}$ code book

**ECS 452** 

**Problem 6.** Consider the following encoding for a systematic linear block code:

- The bit positions that are powers of 2 (1, 2, 4, 8, 16, etc.) are check bits.
- The rest (3, 5, 6, 7, 9, etc.) are filled up with the k data bits.

This is a general of statement about a systematic linear block

- This is a general Each check bit forces the parity of some collection of bits, including itself, to be even.
  - To see which check bits the data bit in position i contributes to, rewrite i as a sum of powers of 2. A bit is checked by just those check bits occurring in its expansion.

We will consider the case when the codeword's length n = 7.

(a) How many bits are check bits?

Hint: How many bit positions are powers of 2?

There are n=7 bits in each codeword.

The check bits are defined to be the bits whose positions are powers of 2.

Among the possible positions (1,2,3,...,7), three positions 2=1, 2=2, 2=4 are powers of 2.

So, there are three check bits. (Note that k=7-3=4 bits)

(b) Find the generator matrix G for this code.

Let p, p, p, be the check bits and

d, d, d, d, d, be the data bits positions that are powers of 2

Then cash codemord is of the form = [2,2,2] x, 2,2,4,4,5,4,4,4

(c) Find the corresponding parity check matrix  ${\bf H}.$ 

$$G = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 1 \end{bmatrix} \Rightarrow H = \begin{bmatrix} 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \end{bmatrix}$$

## Extra Questions

Here are some optional questions for those who want more practice.

**Problem 7** (Carlson and Crilly, 2009, P13.2-1). In mathematical analysis, a function  $d(\underline{\mathbf{x}},\underline{\mathbf{y}})$  is a "true" distance if it satisfies all of the following properties:

- (i) positivity:  $d(\underline{\mathbf{x}},\underline{\mathbf{y}}) \geq 0$  with equality if and only if  $\underline{\mathbf{x}} = \mathbf{y}$
- (ii) symmetry:  $d(\underline{\mathbf{x}}, \mathbf{y}) = d(\mathbf{y}, \underline{\mathbf{x}})$
- (iii) triangle inequality:  $d(\underline{\mathbf{x}}, \underline{\mathbf{z}}) \le d(\underline{\mathbf{x}}, \underline{\mathbf{y}}) + d(\underline{\mathbf{y}}, \underline{\mathbf{z}})$

Is the Hamming distance a "true" distance? (Prove or disprove)

Hint: For the triangle inequality, first consider the number of 1s in  $\underline{\mathbf{u}}$ ,  $\underline{\mathbf{v}}$ , and  $\underline{\mathbf{u}} \oplus \underline{\mathbf{v}}$  and confirm that  $d(\underline{\mathbf{u}}, \underline{\mathbf{v}}) \leq w(\underline{\mathbf{u}}) + w(\underline{\mathbf{v}})$ . Then, from this inequality, replace  $\underline{\mathbf{u}}$  by  $\underline{\mathbf{x}} \oplus \underline{\mathbf{y}}$  and  $\underline{\mathbf{v}}$  by  $\underline{\mathbf{v}} \oplus \underline{\mathbf{v}}$ .

```
(i) Because d(x, y) is the weight of the vector x ⊕ y,
                                    which is simply counting *40 in *0 %,
             it is always 3,0.
    Next, suppose キョン、Then, た⊕と= 0 and d(と, と)=か(と⊕と)=か(0)=0.
          suppose xe #y. Then, there must be at least one position whose corresponding values
                               are different in a and x. This implies there must be at least
                               a 1 in x @ x and hence
                                                   q(4' x) = m(4@ x) >1 >0
         Therefore, d(x, x) = 0 if and only if x = y.
(44) Be cause № ① ½ = ½ ② ± ,
        q(x, x) = m(x⊕x) = m(x⊕x) = q(x, €)
(iii) Triangle inequality
       First we show that for any pair of vector and y,
                                    g(4,4) < m(4) + m(x)
             Recall that d(4, 4) = w (404).
               and that the XOR operation will give a 1 iff we have 100 or 001.
                   Let A be the set
                   of the positions of
                                                            of the positions of
                   15 in -14
                   A = 10(4)
                   Observe that these areas give the positions of 10 in 40 4
           Therefore, w(40 4) = 1 1 ( w(4) + w(4) ( by comparing the area in
      Now, let me = xOX and Y = XOZ.
           From the above inequality 5 we have
                  M(\overline{x} \oplus \overline{\lambda} \oplus \overline{\lambda} \oplus \overline{z}) \leqslant M(\overline{x} \oplus \overline{\lambda}) + M(\overline{\lambda} \oplus \overline{z})
                           (In 6F(2), Y-0Y = 0)
           Hance, d(x, 2) < d(x, x) + d(x, 2)
```

**Problem 8** (Carlson and Crilly, 2009, P13.2-2 and P13.2-3). Consider a block code. Suppose  $\underline{\mathbf{x}}$  is the transmitted codeword and that  $\underline{\mathbf{y}}$  is the vector that results when  $\underline{\mathbf{x}}$  is received with i > 0 bit errors. Use the triangle inequality for the Hamming distance to show that

(a) if the code has  $d_{\min} \geq \ell + 1$  and if  $i \leq \ell$ , then the errors are detectable.

Recall that, to detect error(s), we simply check whether the received vector y is a valid code word.

The errors in x are detectable iff x is not a valid code word.

Consider any codeword a EC that is not se.

From l+1 & d\_min & d(x, e) & d(x, x)+d(x, e) = w(e)+d(x,e) & l+d(x,e)

given by definition of triangle inequality \*(\*) x = e

being d\_min (w(e) & l)

we have  $d(\chi, \leq) > 1 > 0$ . So,  $\chi$  cannot be the same as any code word in C.

(unless  $\chi = \kappa$ , in which case, the is no error to detect.)

Hence, the errors in  $\chi$  are detectable.

(b) if the code has  $d_{\min} \geq 2t + 1$  and if  $i \leq t$ , then the errors are correctable by the minimum distance decoder.

Consider any codeword & &C that is not K.

given by definition of triangle inequality \*(\*) + d(x, c) = w(e) + d(x, c) < t + d(x, c).

given by definition of triangle inequality \*(\*) x = e

(\*\*(e) s t)

we have d(x, e) > ++1 >+

However, d(y, x) = w(e) \*t. So, x is closer to x then any other valid codeword.

Hence, when x is observed, the min distance decoder will output x correcting all the errors in x.
