Friday 9:30-10:30

## Spread spectrum (SS)

- Historically spread spectrum was developed for secure communication and military uses.
To
be $\quad$ - Difficult to intercept for an unauthorized person.
- Easily hidden. For an unauthorized person, it is difficult to even detect their presence in many cases.
- Resistant to jamming.
- Provide a measure of immunity to distortion due to multipath propagation.
- In conjunction with a RAKE receiver, can provide coherent combining of different multipath components.
- Asynchronous multiple-access capability.
- Wide bandwidth of spread spectrum signals is useful for location and timing acquisition.

## Spread spectrum: Applications

- First achieve widespread use in military applications due to
- its inherent property of hiding the spread signal below the noise floor during transmission,
- its resistance to narrowband jamming and interference, and
- its low probability of detection and interception.
- The narrowband interference resistance has made spread spectrum common in cordless phones.
- The basis for both 2nd and 3rd generation cellular systems as well as 2nd generation wireless LANs (WLAN).
- The ISI rejection and bandwidth sharing capabilities of spread spectrum are very desirable in these systems

Definition:

## Spread spectrum conditions

Spread spectrum refers to any system that satisfies the following conditions [Lathi, 1998, p 406 \& Goldsmith, 2005, p. 378]:

1. The spread spectrum may be viewed as a kind of modulation Expansion bandwidth is much greater than the message (baseband) signal bandwidth.
and 2. The spectral spreading is performed by a code that is message independent of the message signal.
are - This same code is also used at the receiver to despread the received signal in order to recover the message signal (from the spread spectrum signal).

- In secure communication, this code is known only to the persons) for whom the message is intended.

## Spread spectrum (2)

- Increase the bandwidth of the message signal by a factor $N$, called the processing gain (or bandwidth spreading factor).
- In practice, $N$ is on the order of 100-1000. [Goldsmith, 2005, p 379]
- N = 128 for IS- 95 [T\&V]
- Wasteful?
- Although we use much higher BW for a spread spectrum signal,
(1) Multiplexing: we can also multiplex large numbers of such signals over the same band.

2. Multiple Access: many users can share the same spread spectrum bandwidth without interfering with one another.

- Achieved by assigning different code to each user.
- Frequency bands can be reused without regard to the separation distance of the users.

## Spread Spectrum (3)

Two forms of spread spectrum (SS)

1. Frequency Hopping (FH) FHSS, $\mathrm{FH} / \mathrm{SS}$

- Hop the modulated data signal over a wide BW by changing its carrier frequency
- BW is approximately equal to $N B$
- $N$ is the number of carrier frequencies available for hopping
- $B$ is the bandwidth of the data signal.

- The most celebrated invention of frequency hopping was that of actress Hedy Lamarr and composer George Antheil in 1942

2. Direct Sequence (DS) DSSS, DS/SS

## UNITED STATES PATENT OFFICE

Filed June 1

For several years beginning in 1997, the boxes of CorelDRAW's software suites were graced by a large Coreldrawn image of Hedy Lamarr.

## SSMA, CDMA, DS/SS

# cot) DS/SS System 

Message signal (data/information signal)

Pseudonoise (PN) sequence. (Think of this as a pseudorandom carrier).

Here, we refer to it as spreading code/ sequence.

## DS/SS DS/SS System (Con't)

Observe that...

- To be able to perform the despreading operation, the receiver must
- know the code sequence $c(t)$ used at the Tx to spread the signal
- synchronize the codes of the received signal and the locally generated code.
- The process of detection (despreading) is identical to the process of spectral spreading.
- Recall that for DSB-SC, we have a similar situation in that the modulation and demodulation processes are identical (except for the output filter).

## Spread spectrum modem

## DS/SS: Spectral Spreading Signalc(t)

- A pseudorandom signal
- Appear to be unpredictable
- Can be generated by deterministic means (hence, pseudorandom)

- The bit rate is chosen to be much higher then the bit rate of $m(t)$.
- The basic pulse in $c(t)$ is called the chip.
- The bit rate of $c(t)$ is known as the chip rate. $=\frac{1}{T_{c}}$
$\int$ - The autocorrelation function of $c(t)$ should be very narrow.
- Small similarity with its delayed version
- Remark: In multiuser (CDMA) setting, the cross-correlation between any two codes $c_{1}(t)$ and $c_{2}(t)$ should also be very small
- Negligible interference between various multiplexed signals.

## Frequency-Domain Analysis

Shifting Properties: $g\left(t-t_{0}\right) \stackrel{\mathcal{F}}{\rightleftharpoons} e^{-j 2 \pi f_{0}} G(f) \quad e^{j 2 \pi f_{0} t} g(t) \stackrel{\mathcal{F}}{\rightleftharpoons} G\left(f-f_{0}\right)$
Modulation: $m(t) \cos \left(2 \pi f_{c} t\right) \stackrel{\mathcal{F}}{\rightleftharpoons} \frac{1}{2} M\left(f-f_{c}\right)+\frac{1}{2} M\left(f+f_{c}\right)$

## DS/SS: Secure Communication

- Secure communication
- Signal can be detected only by authorized person(s) who know the pseudorandom code used at the transmitter.
- Signal spectrum is spread over a very wide band, the signal PSD is very small, which makes it easier to hide the signal within the noise floor

## DS/SS: Jamming Resistance

- Jamming Resistance / Narrowband Interference rejection
- The decoder despreads the signal $y(t)$ to yield $m(t)$.
- The jamming signal $i(t)$ is spread to yield $i(t) c(t)$.
- Using a LPF, can recover $m(t)$ with only a small fraction of the power from $i(t)$.
- Caution: Channel noise will not spread.

## DS/SS: Multipath Fading Immunity

- The signal received from any undesired path is a delayed version of the DS/SS signal.
- DS/SS signal has a property of low autocorrelation (small similarity) with its delayed version, especially if the delay is of more than one chip duration.
- The delayed signal, looking more like an interfering signal, will not be despread by $c(t)$ effectively minimizes the effect of the multipath signals.
- What is more interesting is that DS/SS cannot only mitigate but may also exploit the multipath propagation effect.
- This is accomplished by a rake receiver.
- This receive designed as to coherently combine the energy from several multipath components, which increases the received signal power and thus provides a form of diversity reception.
- The rake receiver consists of a bank of correlation receivers, with each individual receiver correlating with a different arriving multipath component.
- By adjusting the delays, the individual multipath components can be made to add coherently rather than destructively.

Friday $\quad 9: 30-10: 30$

## Binary Random Sequences

- While DSSS chip sequences must be generated deterministically, properties of binary random sequences are useful to gain insight into deterministic sequence design.
- A random binary chip sequences consists of i.i.d. bit values with probability one half for a one or a zero.
- Also known as Bernoulli sequences/trials, "coin-flipping" sequences
- A random sequence of length $N$ can be generated, for example, by flipping a fair coin $N$ times and then setting the bit to a one for heads and a zero for tails.

## Key randomness properties

[Golomb, 1967] Binary random sequences with length $N$ asymptotically large have a number of the properties desired in spreading codes

- Balanced property: Equal number of ones and zeros.
- Should have no DC component to avoid a spectral spike at DC or biasing the noise in despreading
- Run length property:The run length is generally short.
- half of all runs are of length 1
- a fraction $1 / 2^{n}$ of all runs are of length $n$
(Geometric)
- Long runs reduce the BW spreading and its advantages
- Shift property: If they are shifted by any nonzero number of elements, the resulting sequence will have half its elements the same as in the original sequence, and half its elements different from the original sequence.

## Pseudorandom Sequence

- A deterministic sequence that has the balanced, run length, and shift properties as it grows asymptotically large is referred to as a pseudorandom sequence (noiselike or pseudonoise (PN) signal).
- Ideally, one would prefer a random binary sequence as the spreading sequence.
- However, practical synchronization requirements in the receiver force one to use periodic Pseudorandom binary sequences.
- m-sequences
- Gold codes
- Kasami sequences
- Quaternary sequences
- Walsh functions

## m-Sequences

- Maximal-length sequences

Longer name: Maximal length linear shift register sequence.

- A type of cyclic code
- Generated and characterized by a generator polynomial
- Properties can be derived using algebraic coding theory
[Goldsmith, 2005, p 387]
- Simple to generate with linear feedback shift-register (LFSR) circuits
- Automated
- Approximate a random binary sequence.
- Disadvantage: Relatively easy to intercept and regenerate by an unintended receiver

## m-sequence generator

- The feedback taps in the feedback shift register are selected to correspond to the coefficients of a primitive
polynomial.

$$
\begin{aligned}
g(x) & =x^{3}+x^{2}+1 \quad(\text { Degree: } \mathrm{r}=3) \\
& =1+0 x+1 x^{2}+1 x^{3}
\end{aligned}
$$

The $g_{i}$ 's are coefficients of a primitive polynomial.
1 signifies closed or a connection and
Binary sequences drawn from the alphabet $\{0,1\}$ are shifted through the shift register in response to clock pulses. The particular 1 s and 0 s occupying the shift register stages after a clock pulse

| Time | $R_{0}$ | $R_{1}$ | $R_{2}$ |
| :---: | :---: | :---: | :---: |
| 0 | 1 | 0 | 0 |
| 1 | 0 | 1 | 0 |
| 2 | 1 | 0 | 1 |
| 3 | 1 | 1 | 0 |
| 4 | 1 | 1 | 1 |
| 5 | 0 | 1 | 1 |
| 6 | 0 | 0 | 1 |
| 7 | 1 | 0 | 0 |

Sequence repeats from here onwards

## GF(2)

- Galois field (finite field) of two elements
- Consist of
- the symbols 0 and 1 and
- the (binary) operations of
- modulo-2 addition (XOR) and
- modulo-2 multiplication.
- The operations are defined by

$$
\left.\begin{array}{rrrrl}
0 \oplus 0 & =0, & 0 \oplus 1 & =1, & 1 \oplus 0
\end{array}\right)
$$

## Sample Exam Question

Draw the complete state diagrams for linear feedback shift registers (LFSRs) using the following polynomials. Does either LFSR generate an m-sequence?

1. $x^{3}+x^{2}+1$
2. $x^{3}+x^{2}+x+1$

Nonmaximal linear feedback shift register $x^{3}+x^{2}+x+1$

## Equivalent Statements

The three statements below are equivalent:

1. Polynomial $g(x)$ generates $m$-sequence
2. Polynomial $g(x)$ is a primitive polynomial.
3. The state diagram of the LFSR circuit generated by $g(x)$ visits all non-zero states in one cycle.

Implication:
We can use statement " 3 " to test whether a polynomial $g(x)$ is primitive.

For this class, we use " 3 " as the definition of being a primitive polynomial.

## m-Sequences: More properties

1. The contents of the shift register will cycle over all possible $2^{r}-1$ nonzero states before repeating.
2. Contain one more 1 than 0 (Slightly unbalanced) $<_{2}^{r-1}$
3. Shift-and-add property: Sum of two (cyclic-)shifted m-sequences is another (cyclic-)shift of the same m-sequence
4. If a window of width $r$ is slid along an m -sequence for $N=2^{r}-1$ shifts, each $r$ tuple except the all-zeros r-tuple will appear exactly once vun length
(5.) For any $m$-sequence, there are - One run of ones of length $r$

- One run of zeros of length $r-1$

- One run of ones and one run of zeroes of length r-2 r-2 2
- Two runs of ones and two runs of zeros of length r-3 $r-3 \quad 2^{2}$
- Four runs of ones and four runs of zeros of length r-4 $r-4 \quad 2^{3}$
-... $r-i 2_{r-2}^{i}$
- $2^{\text {r-3 }}$ runs of ones and $2^{\text {r-3 }}$ runs of zeros of length $1 \quad 1 \quad 2^{r-2} \quad 1 / 2$

$$
\begin{aligned}
\text { total } x \text { runs } & =1+1+2+2^{2}+2^{3}+\cdots+2^{r-2} \\
& =2^{r-1}
\end{aligned}
$$

\hline-1 & 1 & 1 \\
-1 & 1 & -1 \\
\hline & -1
\end{array} \quad \sum=-1 \quad \begin{array}{ccc}
1 & -1 & 1 \\
1 & 1 & -1
\end{array}
$$

## Autocorrelation and PSD

- (Normalized) autocorrelations of maximal sequence and random binary sequence.

- Power spectral density of maximal sequence.
$R_{c}(\tau)=\frac{1}{T_{0}} \int_{T_{0}} x(t) x(t+\tau) \mathrm{d} t= \begin{cases}\left(1-\frac{|\tau|}{T_{\varepsilon}}\right)\left(1+\frac{1}{N}\right)-\frac{1}{N}, & |\tau| \leq T_{c} \\ -\frac{1}{N}, & T_{c}<|\tau| \leq \frac{N-1}{2} T_{c}\end{cases}$
(4.2)
where the integration is over any period, $T_{0}=N T_{c}$.

$$
S_{c}(f)=\sum_{m=-\infty}^{\infty} P_{m} \delta\left(f-m f_{0}\right), f_{0}=1 / N T_{c},
$$

where

$$
P_{m}=\left\{\begin{array}{l}
{\left[(N+1) / N^{2}\right] \operatorname{sinc}^{2}(m / N), m \neq 0, \operatorname{sinc}(x)=(\sin \pi x) /(\pi x)} \\
1 / N^{2}, m=0
\end{array}\right.
$$
