## UMTS

- Universal Mobile Telecommunications System (UMTS)
- The research activity on UMTS started in Europe at the beginning of the 1990s.
- Even before the earliest 2G systems arrived on the market
- Designed to support wideband services with data rates up to $2 \mathrm{Mbit} / \mathrm{s}$.
- Developed from GSM
- Keep the core network more-or-less intact
- Change the air interface to use CDMA
- Compatibility between UMTS and GSM:
- Most UMTS mobiles also implement GSM, and the network can hand them over from a UMTS base station to a GSM one if they reach the edge of the UMTS coverage area.
- However, network operators cannot implement the two systems in the same frequency band, so they are not fully compatible with each other.

## Bandwidth Comparison

| Generation | Transmission Bandwidth | Standard |
| :--- | :--- | :--- |
| 1G | 25 and 30 kHz |  |
| 2G | 200 kHz | GSM |
|  | 1.25 MHz | IS-95 (CDMA) |
| 2.5G | 1.25 MHz | CDMA2000 1X-RTT |
| 3G | 5 MHz | WCDMA and CDMA2000 3X-RTT |
| "4G" | Up to 20 MHz | LTE and WiMAX (802.16) <br> Wi-Fi (802.11a/g) |

Wider and wider radio frequency bands!

## UMTS: FDD

- The chip rate for spectrum spreading is $3.84 \mathrm{Mc} / \mathrm{s}$.
- The maximum transmitter power of the user equipment is in the range of 21 to 33 dBm (that is, 125 mW to 2 W )

$$
\left(10^{2 / 1 / 0} \mathrm{~mW}\right)\left(10^{33 / 10} \mathrm{~mW}\right)
$$

$(0 \mathrm{dBm}$ or $\mathrm{dBmW}=1 \mathrm{~mW})$

[Karim and Sarraf, 2002, Fig 6-1]

## Review: CDMA

- Two Users. Suppose the code length $=N$. Taken from $\mathbf{H}_{N}$.
- User 1 uses code $\underline{c}_{1}$. Want to send messages $a_{1}, a_{2}, a_{3}, a_{4}, \ldots$
- Send $\left.\underline{x}_{1}=a_{1} \underline{\underline{C}}_{1} a_{2} \underline{\underline{c}}_{1} a_{3} \underline{\underline{c}}_{1} \quad a_{4} \underline{\underline{c}}_{1} \cdots\right]$
- User 2 uses code $\underline{\underline{c}}_{2}$. Want to send messages $b_{1}, b_{2}, b_{3}, b_{4}, \ldots$
- Send $\underline{X}_{2}=\left[b_{1} \underline{C}_{2} b_{2} \underline{\underline{C}}_{2} b_{3} \underline{c}_{2} b_{4} \underline{C}_{2} \cdots\right]$
- Receiver gets $\underline{r}=\underline{x}_{1}+\underline{x}_{2}$
- To recover $\mathrm{a}_{1}$, calculate $\frac{1}{N}\left\langle\underline{r}(1: N), \underline{c}_{1}\right\rangle$
- To recover $\mathrm{b}_{1}$, calculate $\frac{1}{N}\left\langle\underline{r}(1: N), \underline{c}_{2}\right\rangle$
- To recover $a_{2}$, calculate $\frac{1}{N}\left\langle\underline{r}((N+1):(2 N)), c_{1}\right\rangle$

Observe that, for successful transmission, we need

$$
\underline{C}_{1} \perp \underline{C}_{2}
$$

or, equivalently,

$$
\left\langle\underline{c}_{1}, \underline{c}_{2}\right\rangle=0
$$

## Ex: CDMA

$$
\mathbf{H}_{4}=\left[\begin{array}{rrrr}
1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 \\
1 & -1 & -1 & 1
\end{array}\right]
$$

- Two Users. Suppose the code length $=4$. Taken from $\mathbf{H}_{4}$.
- User 1 uses code $\underline{c}_{1}$. Want to send messages $a_{1}, a_{2}, a_{3}, a_{4}, \ldots$

- User 2 uses code $\underline{c}_{2}$. Want to send messages $b_{1}, b_{2}, b_{3}, b_{4}, \ldots$

- Receiver gets $\underline{r}=\underline{X}_{1}+\underline{x}_{2}$
- To recover $a_{1}$, calculate $\frac{1}{4}\left\langle\underline{( }(1: 4), c_{1}\right\rangle$
- To recover $\mathrm{b}_{1}$, calculate $\frac{1}{4}\left\langle\underline{( }(1: 4), \underline{c}_{2}\right\rangle$
- To recover $\mathrm{a}_{2}$, calculate $\frac{1}{4}\left\langle\underline{-}(5: 8), \mathrm{c}_{1}\right\rangle$

## OVSF (1)

- Channelization codes used in UMTS W-CDMA and cdma2000 are variable-length Walsh codes, also known as orthogonal variable spreading factor (OVSF) codes.
- The spreading factors in UMTS may vary from 4 to 256 chips on uplink channels and from 4 to 512 chips on downlink channels. - In cdma2000, OVSF codes used on traffic channels may vary from 4 to 128 chips.
- Comparison: IS-95 uses a set of 64 fixed-length Walsh codes to spread forward physical channels. In the reverse direction, they are used for orthogonal modulation where every six symbols from the block interleaver output are modulated as one of 64 Walsh codes.

## Ex: Multiple Code Lengths

- Two Users. Suppose the code length $=4$.
- User 1 uses code $\underline{c}_{4,2}$. Want to send messages $a_{1}, a_{2}, a_{3}, a_{4}, \ldots$
- Send $\underline{x}_{1}=\left[a_{1} \underline{C}_{4,2} a_{2} \underline{c}_{4,2} a_{3} \underline{c}_{4,2} a_{4} \underline{\mathcal{C}}_{4,2} \cdots\right]$
- User 2 uses code $\underline{c}_{8,7}$. Want to send messages $b_{1}, b_{2}, b_{3}, b_{4}, \ldots$
- Send $\underline{X}_{2}=\left[\square b_{1} \underline{c}_{8,7} \quad b_{2} \underline{c}_{8,7} \quad \cdots\right]$
- Receiver gets $\underline{r}=\underline{x}_{1}+\underline{\chi}_{2}$
- To recover $a_{1}$, calculate $\frac{1}{4}\left\langle\underline{r}(1: 4), \underline{c}_{4,2}\right\rangle=a_{1}+\frac{b_{1}}{4}\left\langle\underline{c}_{\varepsilon_{8}, 7}(1: 4), \underline{c}_{4,2}\right\rangle$
- To recover a 2 , calculate $\frac{1}{4}\left\langle\underline{( }(5: 8), \underline{c}_{4,2}\right\rangle=a_{2}+\frac{b_{1}}{4}\left\langle\underline{c}_{\varepsilon_{8}, 7}(5: 8), \underline{c}_{4,2}\right\rangle$
- To recover $b_{1}$, calculate $\frac{1}{8}\left\langle\underline{r}(1: 8), \underline{s}_{8,7}\right\rangle=\frac{a_{1}}{8}\left\langle{\underline{\varepsilon_{8,7}}}^{\left.(1: 4), \underline{c}_{4,2}\right\rangle+\frac{a_{2}}{8}\left\langle\underline{c}_{\varepsilon_{8},}(5: 8), \underline{c}_{4,2}\right\rangle+b_{1}}\right.$
- To recover $b_{2}$, calculate $\frac{1}{8}\left\langle\underline{( }(9: 16), c_{8,7}\right\rangle$

Observe that, for successful transmission, we need $\left\langle\underline{c}_{8,7}(1: 4), \underline{c}_{4,2}\right\rangle=\left\langle\underline{c}_{8,7}(5: 8), \underline{c}_{4,2}\right\rangle=0$
So, we have some idea of how to define orthogonality for codes with different lengths.

## Ex: Multiple Code Lengths

- Two Users. Code lengths are not the same
- User 1 uses code $\underline{c}_{4,2}=\left[\begin{array}{llll}1 & -1 & 1 & -1\end{array}\right]$.

- User 2 uses code $\underline{c}_{8,7}=\left[\begin{array}{llllllll}1 & -1 & -1 & 1 & -1 & 1 & 1 & -1\end{array}\right]$.
- Send $\underline{x}_{2}=\left[b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{1} b_{2}\right]$
- Receiver gets $\underline{r}=\underline{X}_{1}+\underline{X}_{2}$
- To recover $a_{1}$, calculate $\frac{1}{4}\left\langle\underline{r}(1: 4), c_{4,2}\right\rangle$
- To recover $\mathrm{a}_{2}$, calculate $\frac{1}{4}\left\langle\underline{r}(5: 8), \boldsymbol{c}_{4,2}\right\rangle$
- To recover $b_{1}$, calculate $\frac{1}{8}\left\langle\underline{r}(1: 8), \underline{\varepsilon}_{8,7}\right\rangle$
- To recover $b_{2}$, calculate $\frac{1}{8}\left\langle\underline{\underline{r}}(9: 16), \mathrm{c}_{8,7}\right\rangle$

## OVSF (2)

- Similar to Walsh sequences
- Arranged and numbered in a different way
- Use a tree structure
- For each spreading factor $\mathbf{S F}=1,2,4, \ldots$, which is a power of 2, there are $N=$ SF orthogonal codes obtained by the recursion relations:

$$
\begin{aligned}
c_{2 S F, 2 m} & =\left[c_{S F, m}, c_{S F, m}\right], m=0,1, \ldots, S F-1 . \\
c_{2 S F, 2 m+1} & =\left[c_{S F, m},-c_{S F, m}\right], m=0,1, \ldots, S F-1 .
\end{aligned}
$$

- Different data rates are supported on a physical channel by simply changing the spreading factor of the associated code.

## Tree structure for OVSF codes (1)

## Tree structure for OVSF codes (2)

## Code allocation rules (1)

- OVSF codes can be applied to realize connections with different data rates by varying the spreading factor.
- Smaller SF = Faster data rate
- To have connections with different data rates, need some rules (for selecting the codes) to maintain orthogonality
- Code blocking property: If a certain code is already used for one connection, neither this code nor a code that is a descendant or an ancestor of this code (on the tree) is allowed to be used for another connection
- These codes are not orthogonal to the already allocated one.

## Code allocation rules (2)

Codes not allowed to be assigned to other connections

## Code allocation rules (3)

- Two OVSF codes are orthogonal if and only if neither code lies on the path from the other code to the root.
- If, for example, code $\mathrm{c}_{4,1}$ is in use, another connection with a different data rate is not allowed to use the encircled codes.
- Other cades can still be used.
- If, for example, the second connection has twice the data rate of the first one, it has to select the code $\mathrm{c}_{2,1}$.
- Within the period of one data bit of connection 1, connection 2 transmits two data bits.
